Grundlagenforschung

# The Pierre Auger Observatory

- Malargüe, Argentina
- Hybrid detector for extensive air showers
- >1600 SD tanks cover 3000 km<sup>2</sup>
- 4 FD eyes with each 6 telescopes, FOV: 180° x 30°
- CR energy range: >10<sup>18</sup> eV
- Complete since June 08

# High Elevation Auger Telescopes (HEAT)

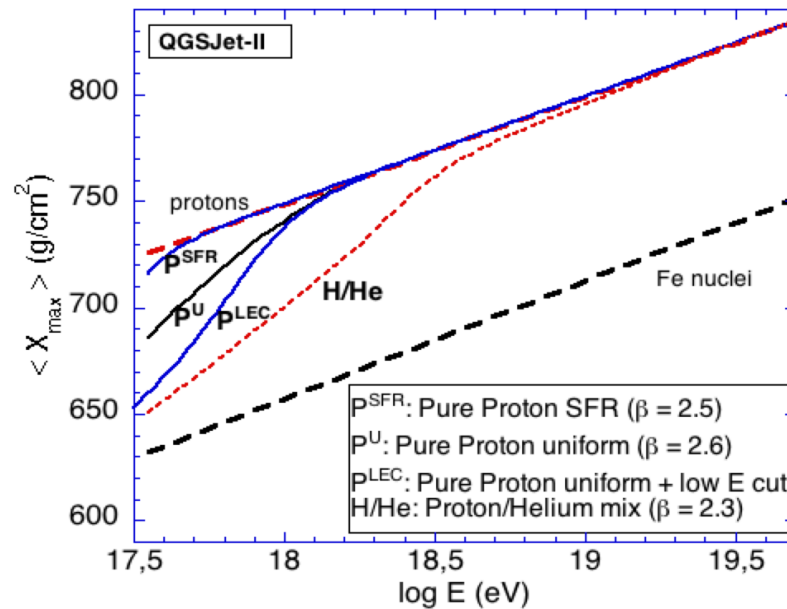

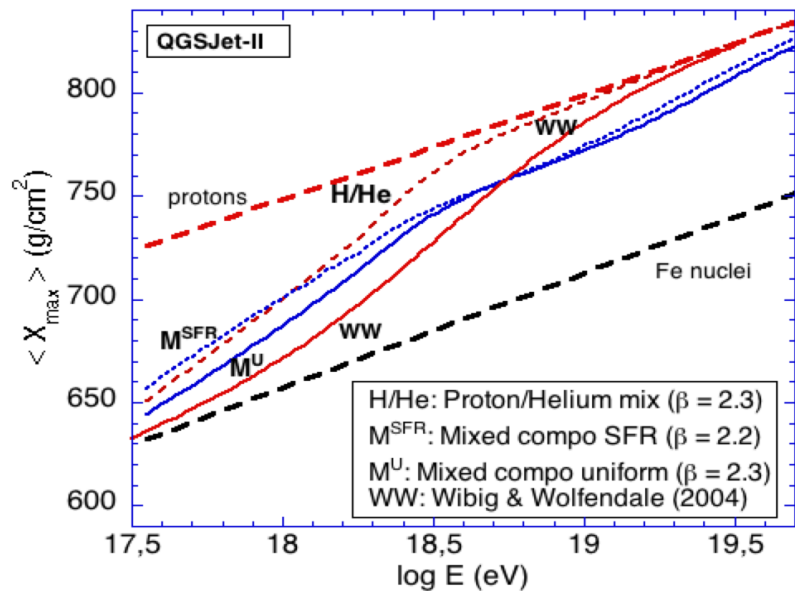

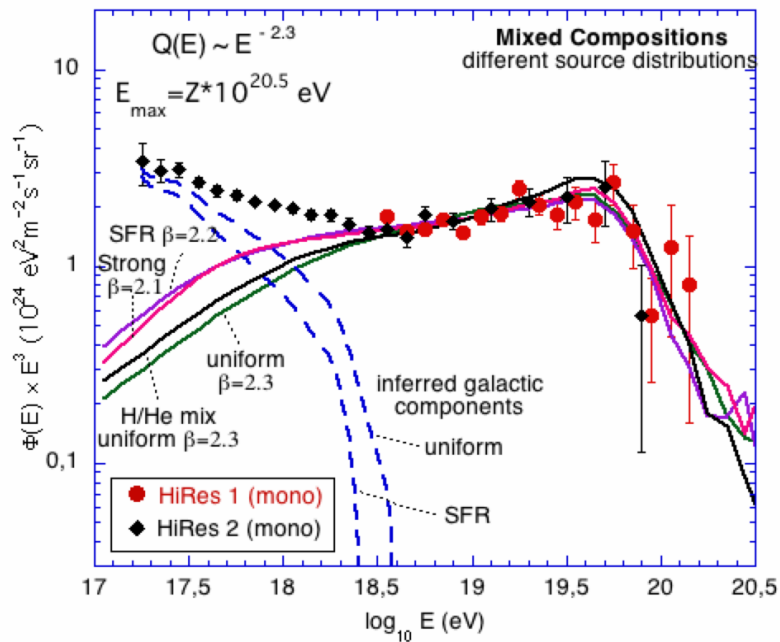

- 3 new telescopes
- Close to Coihueco eye
  - crosschecks
  - combined reconstruction
- AMIGA infill in FOV
- Elevation  $30^{\circ}$ - $60^{\circ}$
- Still under construction, first data by end of 2008

# HEAT Field of View

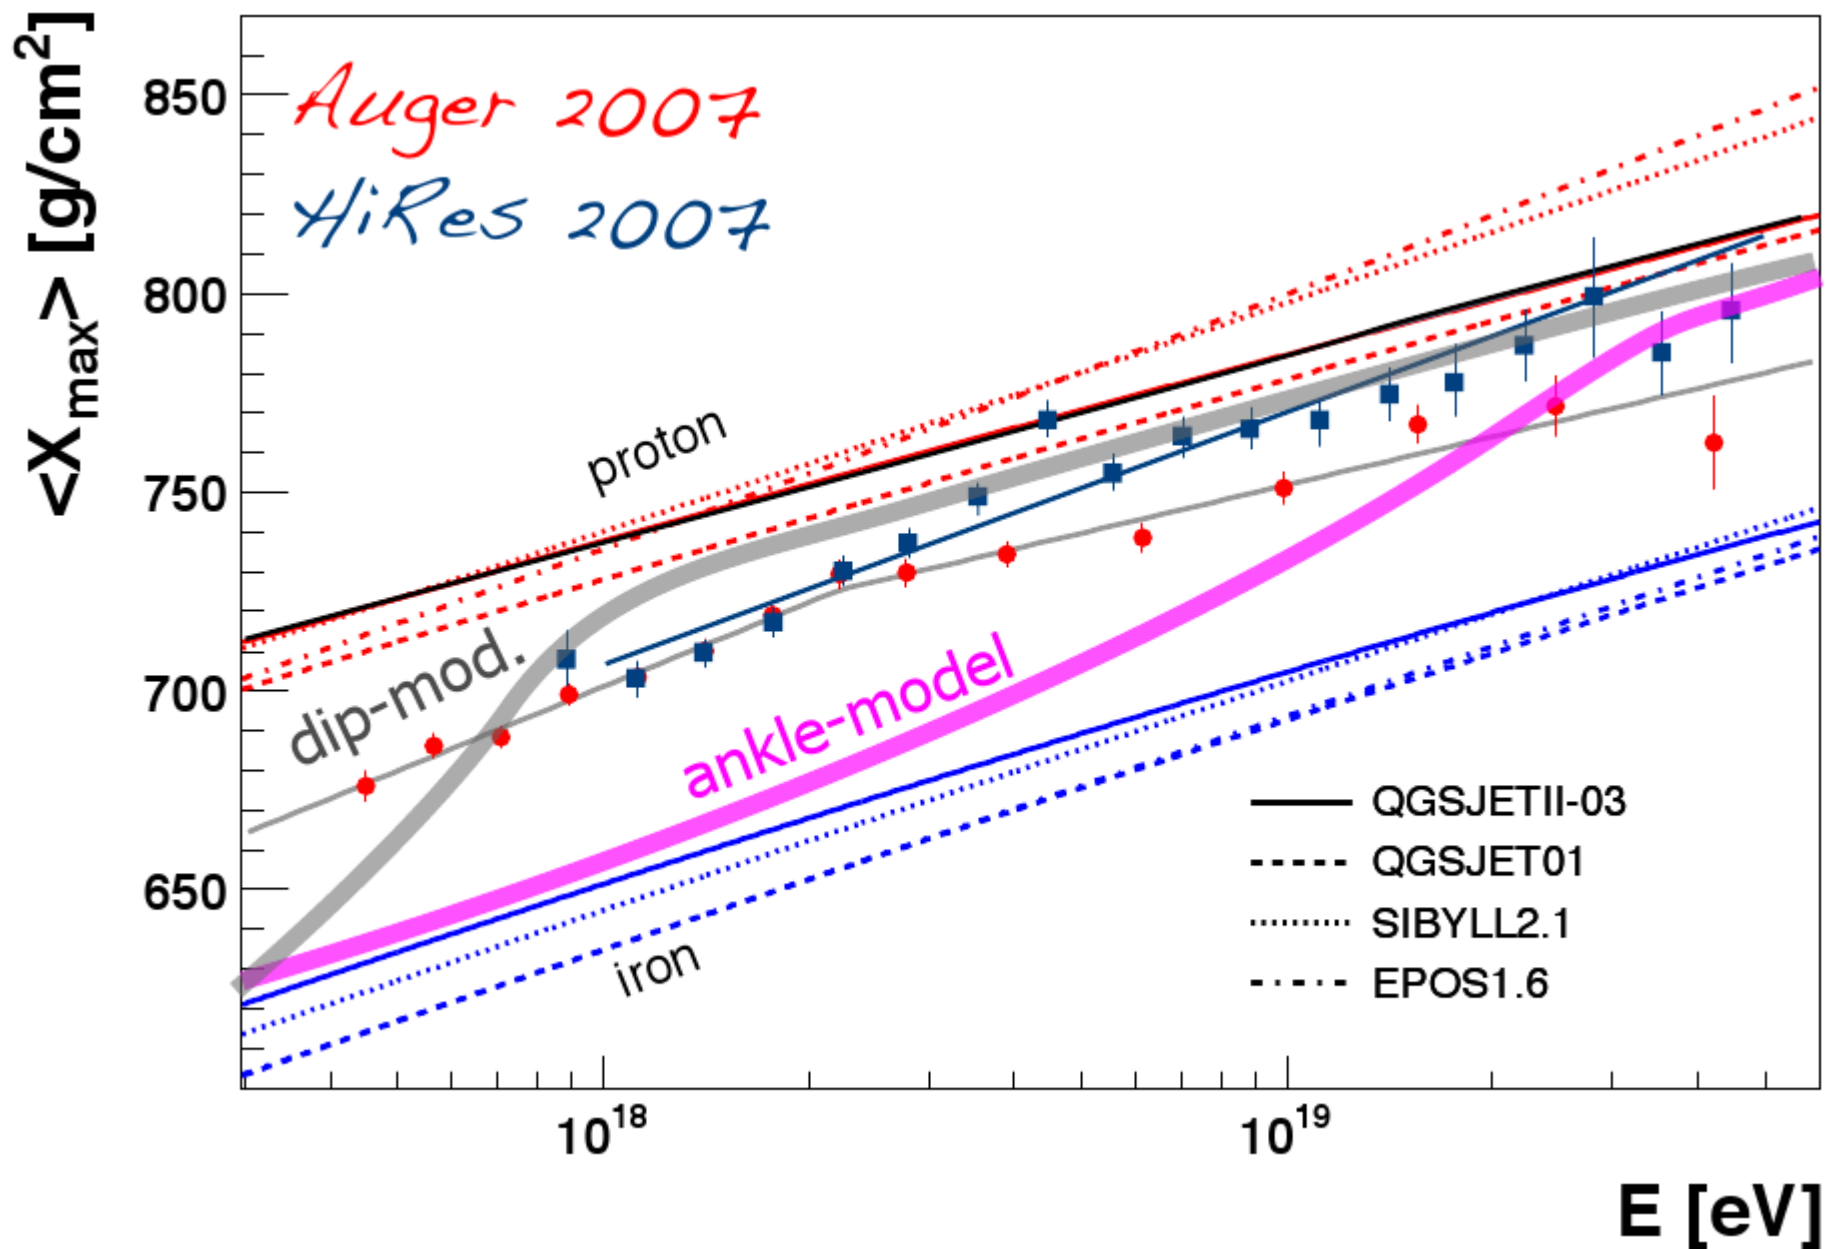

# Physical Motivation I

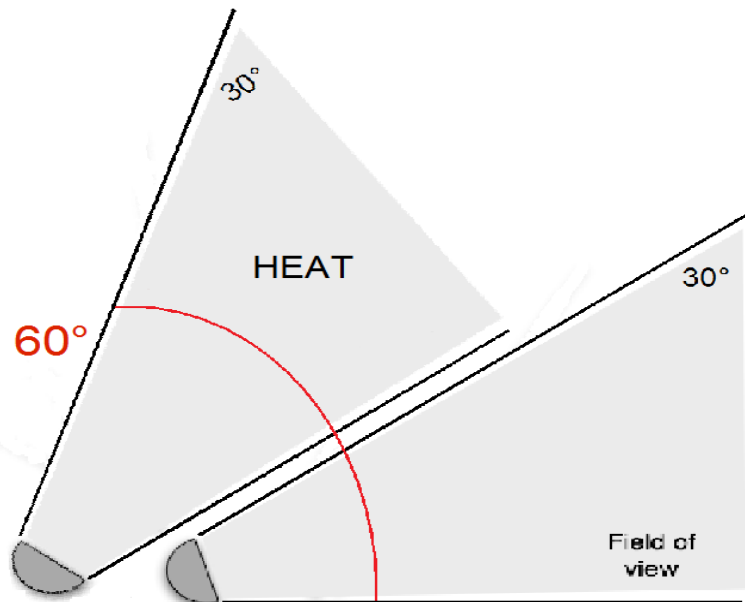

Allard, Olinto, Parizot; astro-ph/0703633

# Physical motivation II

# Bias at low energies

- Shower reconstruction needs maximum in field of view
- At low energies ( $<10^{19}$  eV) measurements up to  $30^\circ$  are biased:
  - fainter fluorescence light
  - lower  $X_{\max}$
  - different  $X_{\max}$  for iron and proton

# Simulations

- CONEX proton and iron showers.
- Steps of 0.25 in  $\log(E)$  from  $10^{16}$  to  $10^{19}$  eV.
- Uniform azimuth angular distribution.
- Zenith angle from  $0^\circ$  to  $70^\circ$  with  $dN/d\cos\theta \sim \cos\theta$ .
- Shower cores distributed on a half circular area around the FD.

# An example event

$E = 10^{17.5}$  eV

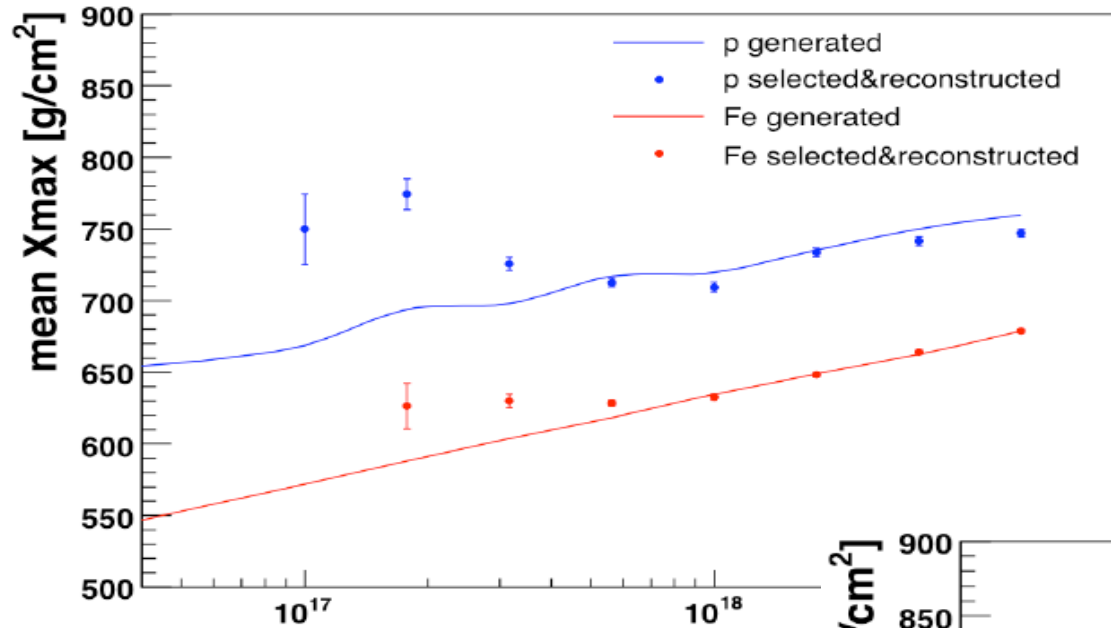

$D = 1.2$  km

# Results I – Acceptance Comparison

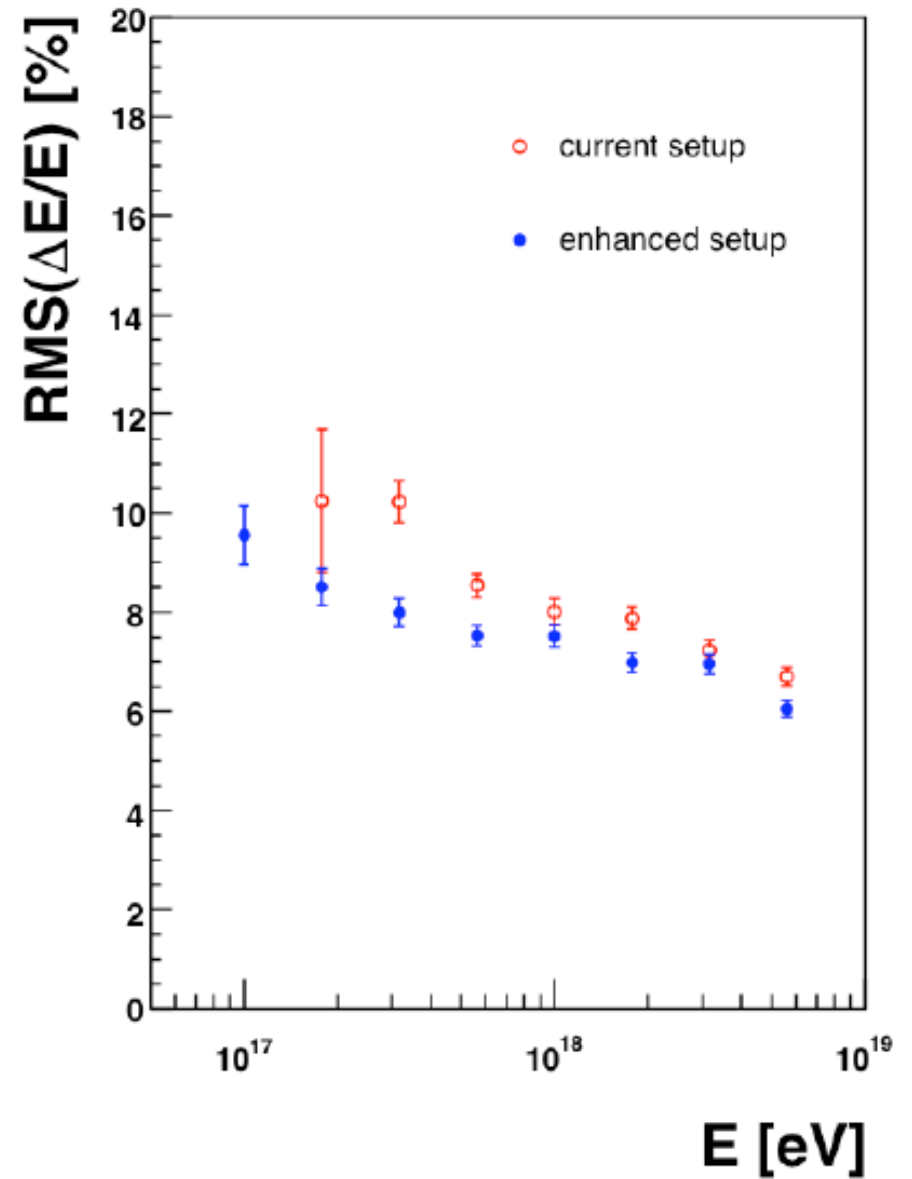

# Results II - Xmax

Enhanced Setup

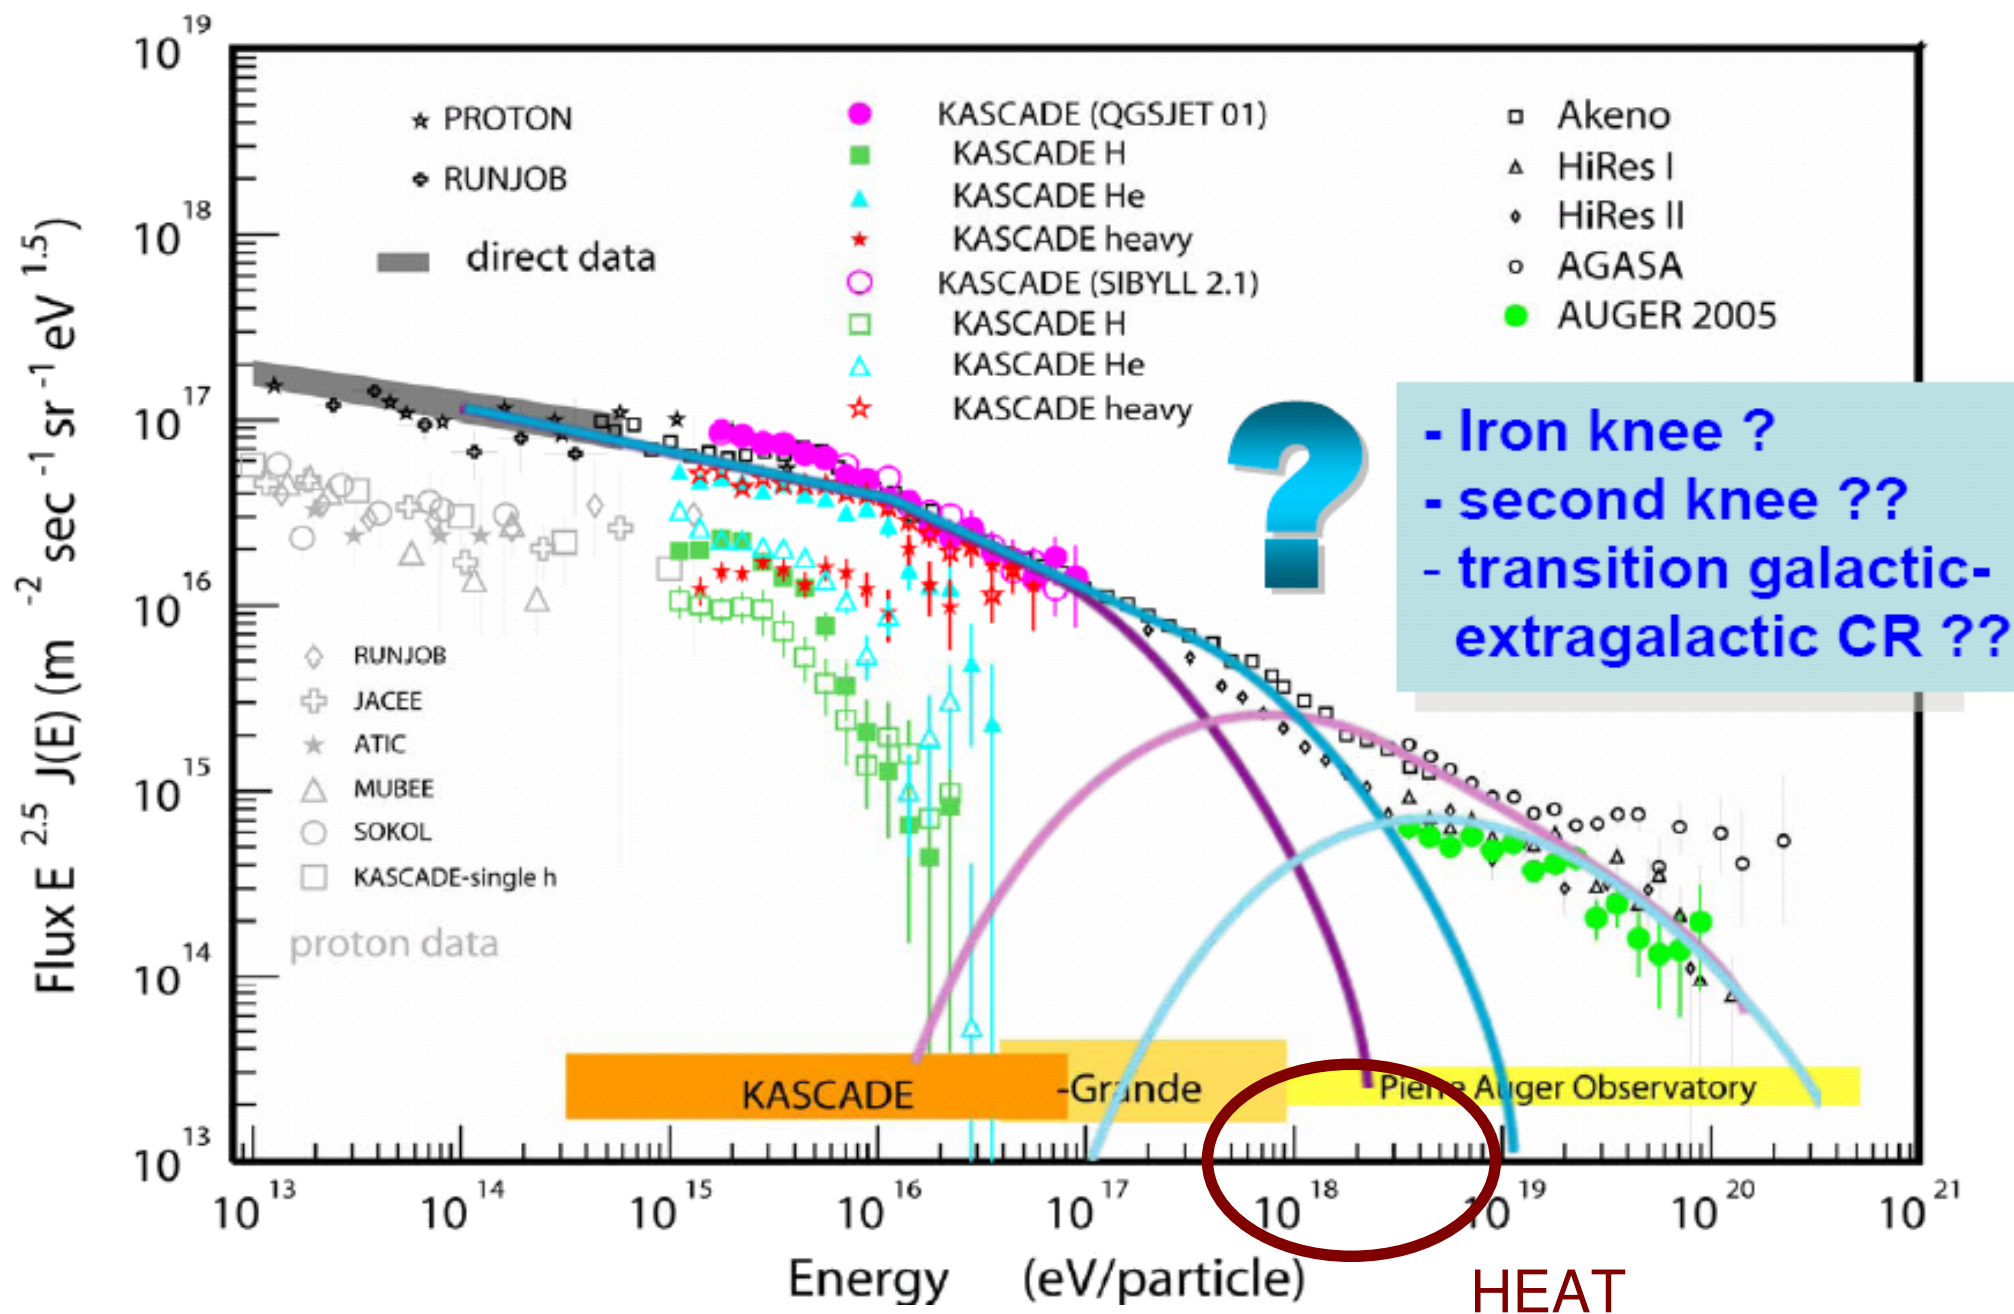

# Results III – Xmax & Energy Resolution

# Summary and Outlook

- HEAT extends the spectrum of Auger down to a few  $10^{17}$  eV.
- Allows to test different models for transition from galactic to extra-galactic CR.
- Resolves problem with biased reconstruction at low energies.
- First data by end of 2008.

# Physical Motivation I

# Physical Motivation II

- Transition from iron to proton?
